Medication documentation in the Netherlands

Practical experiences and future plans
22/5/2017

- **AORTA**: national infrastructure for health data
 - **Medication Documentation**: past, present and future (shifting scope... shifting standards)
 - **Operational**: Electronic Medication Record (v3)
 - **Implementation**: Medication Process (CDA)
 - **Planned**: Personal Health Environment (FHIR)
 - Building blocks for standards
 - Lighting the FHIR...
-

39

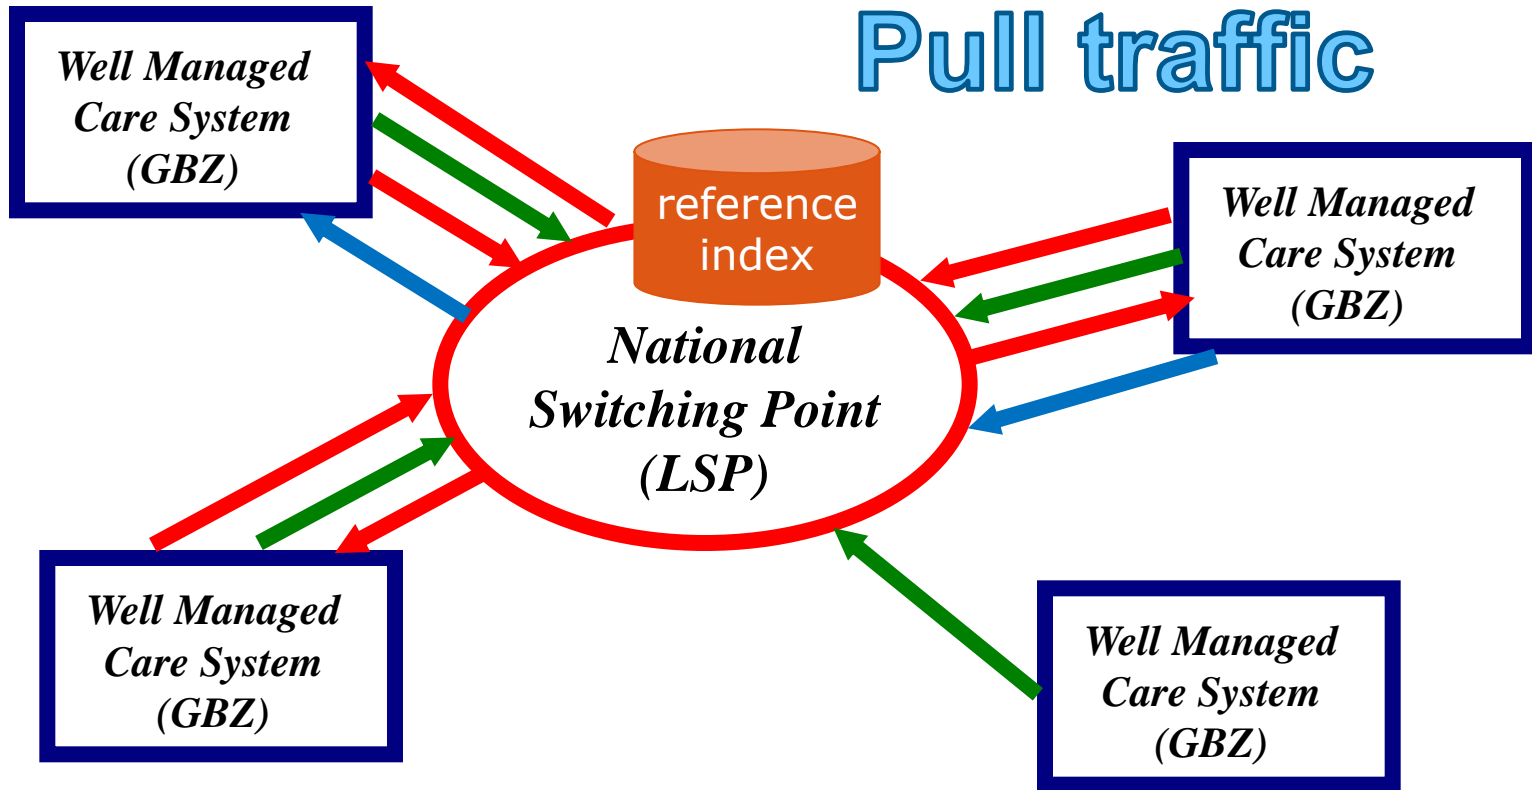

- National infrastructure for the standardized electronic exchange of healthcare data
 - Initially funded by ministry of health
 - Political crisis 2011 → government pulls out
 - Since 2012: funded by private insurers
 - Operated and innovated by VZVZ, an organisation of all healthcare providers
 - Participation optional (patients and providers)
-

AORTA: how it works

Push traffic

Index updates

Pull traffic

The Electronic Medication Record

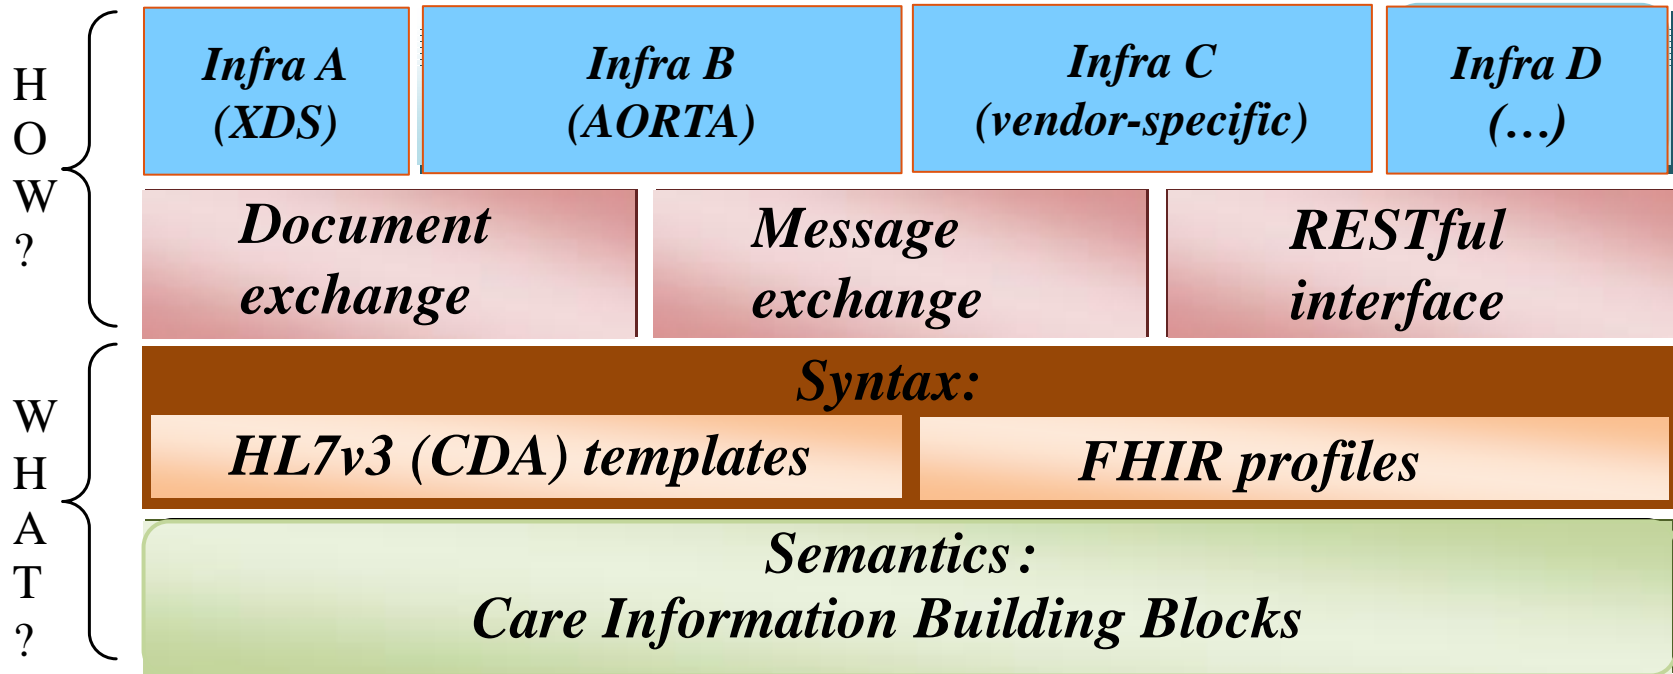

- Retrieval of **medication dispense data** from pharmacies by pharmacies, GPs and hospitals
- Includes allergies and contra-indications
- Replaced existing regional infrastructure
- Standard: based on **HL7v3 messaging**
- Currently 200.000+ messages per week

Medication Process (current national program)

- Exchange of a **complete medication overview between care providers**
- Covers the complete medication cycle
- Based on new conceptual building blocks
- Standard: **CDA-compliant templates**
(implementable building blocks)

- ◀ Bidirectional exchange of information **between patients and their providers**
 - ◀ Scope initially medication, allergies, lab and self-testing (later expanded to other data)
 - ◀ Based on same conceptual building blocks
 - ◀ Standard: **profiles for FHIR resources** (implementable building blocks)
-

Building blocks for standards

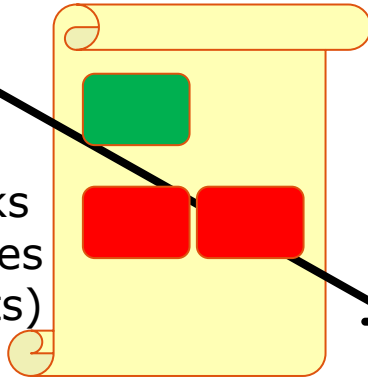

**AORTA 8:
infrastructure for the exchange of
standardized building blocks of health data**

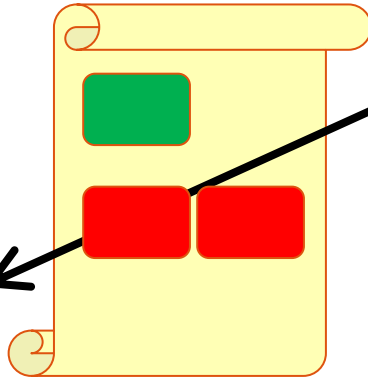

Push mechanism CDA documents

CDA document
with building blocks
as document entries
(clinical statements)

routing by LSP

Pull mechanism query messages

Generic query with "context"
parameters:
Patient, Context [, Period, Source]
(= Who? What? When? Where?)

Selection and Determination Service
Context + Authorisation
→ selection of building blocks
from source systems

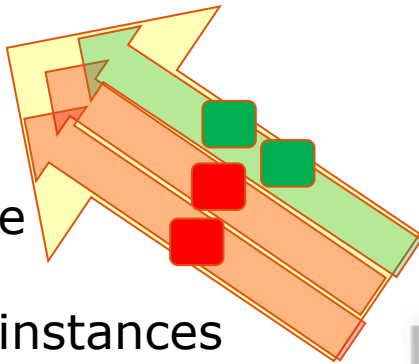

Queries for building blocks
parameters: Patient [, Period],
filters based on context and authorisation

Pull mechanism response messages

Query response with **bundled** building block instances

Flexibility
on the requesting side
Stability
on the source side

Query responses with building block instances (as CDA clinical statements)

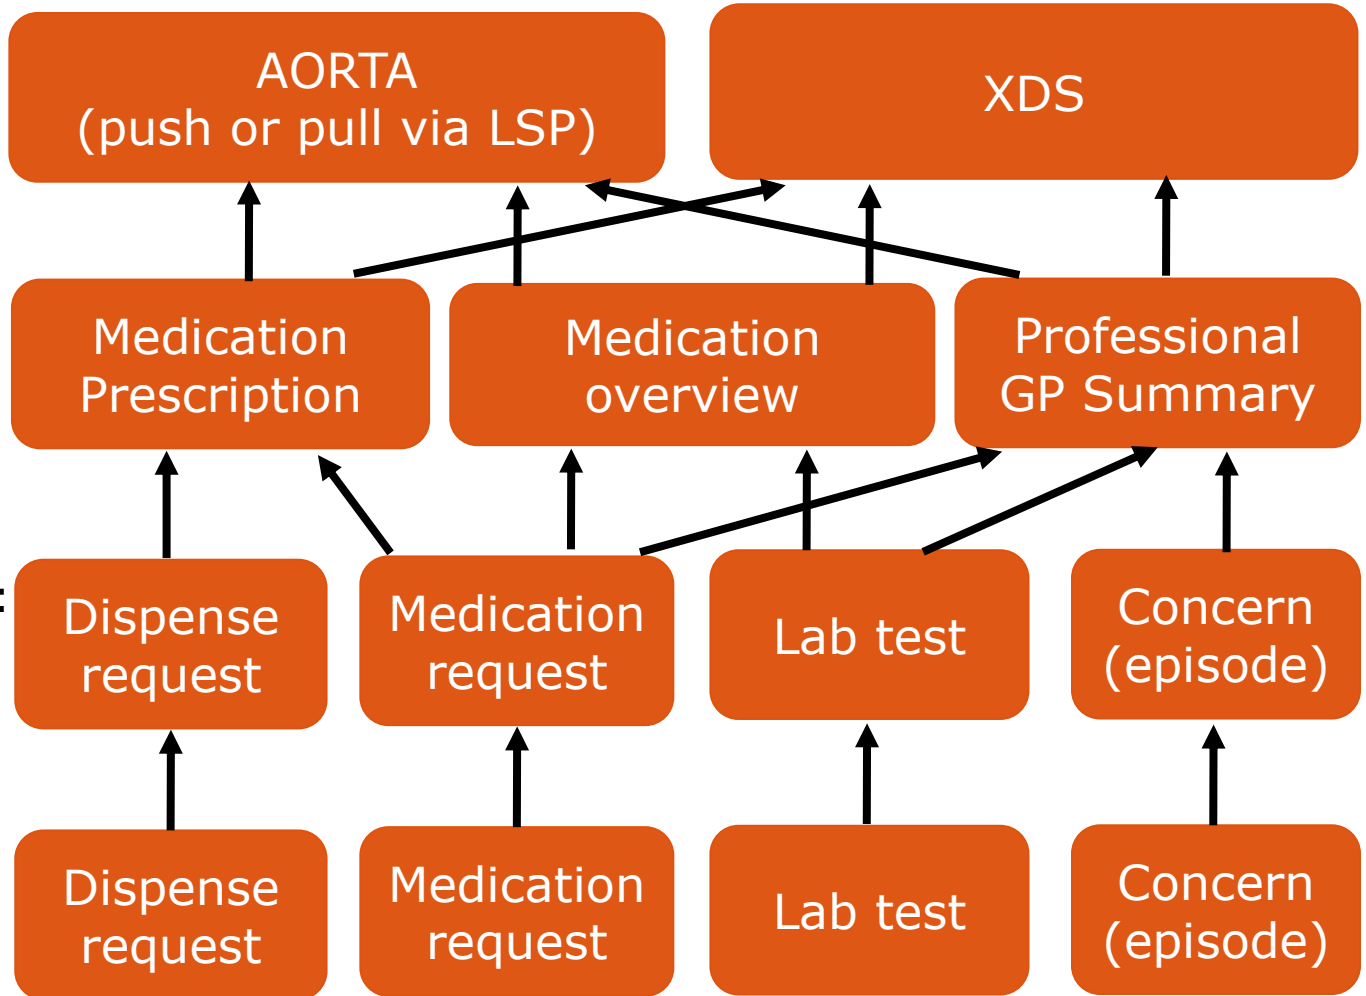

Levels of building blocks

Infrastructural:
More and more content-agnostic

Exchangeable:
Context-specific information sets

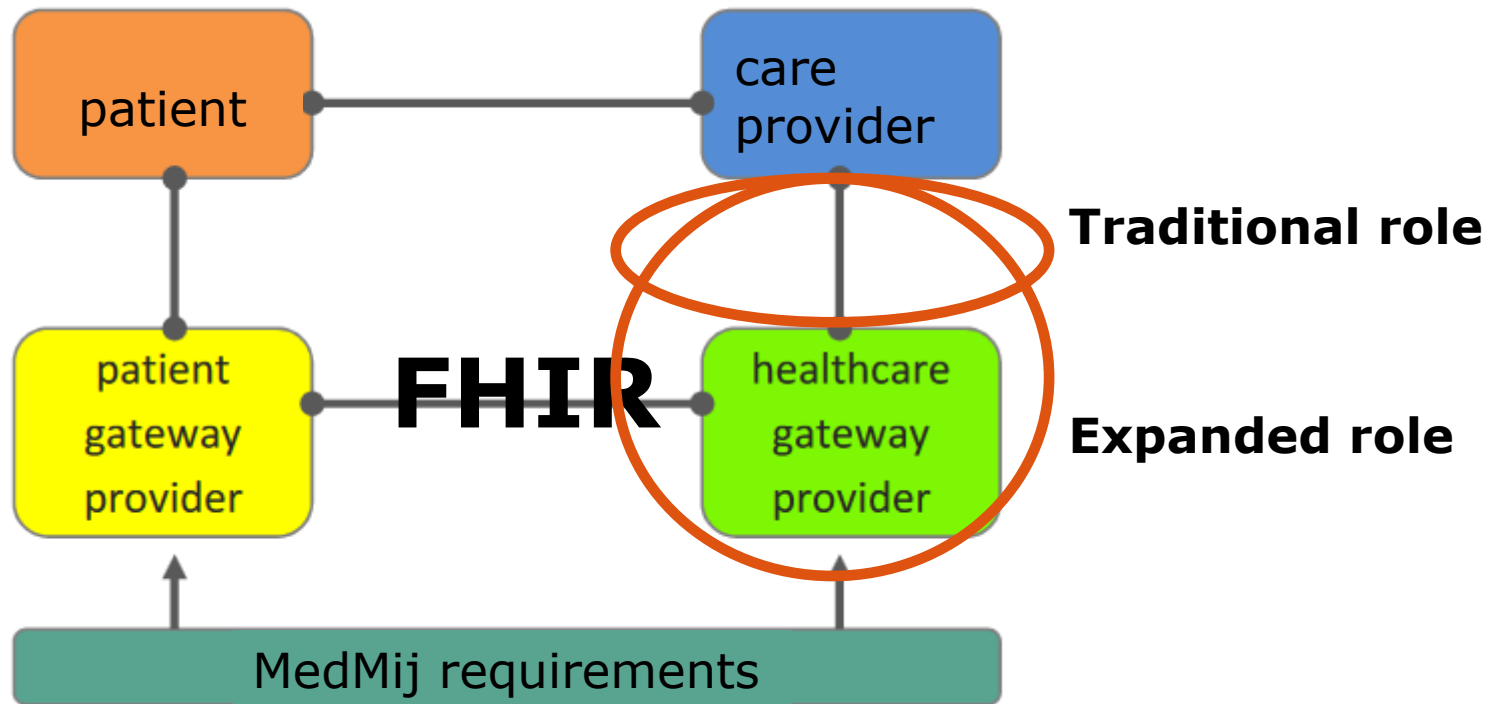

Implementable:
HL7 templates or FHIR profiles

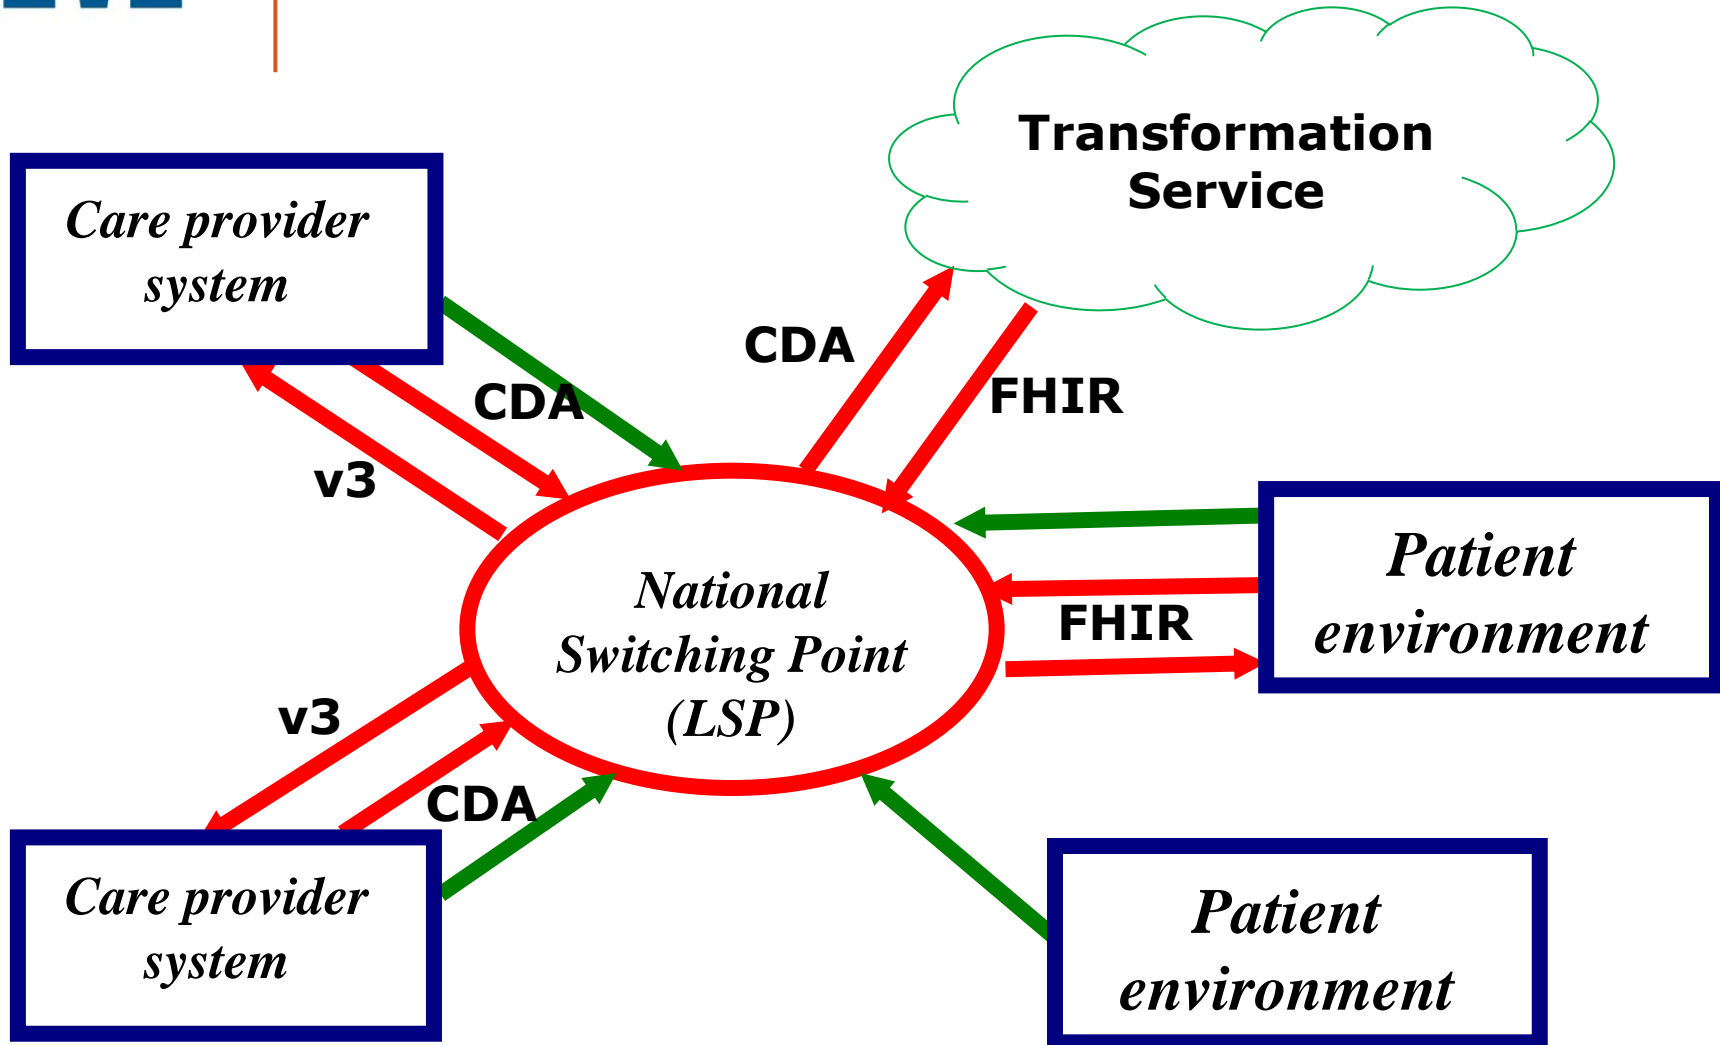

Conceptual:
Care Information Building Blocks

MedMij (patient interface): finding a role for AORTA

MedMij 4-corner model

The bottom line for the Netherlands

- Dutch advantages:
 - national infrastructure AORTA
 - universal coding system for medication
 - Dutch challenges:
 - install base of existing interfaces
 - gap between 'old' and 'new' system vendors
 - co-existence of v3 messaging, CDA and FHIR
 - need for transformation until full migration
 - lack of coordination in standards development
 - investment in projects without a shared strategy
-
